### So You Want a Dancing Duck.

- A quick and effective way to animate many characters with a many motions
- An overview of the process includes:
  - Gather model and motion
  - Match model and motion poses
  - Bind the model to the motion
  - Tweak the results using constraint-based motion editing techniques

---

---

---

---

---

---

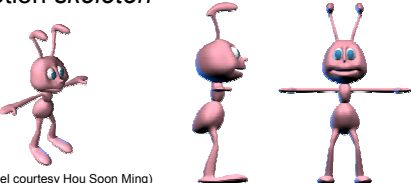

---

---

### Start With a Model.

- Off the web
- Created from scratch
- Must be able to bind to a hierarchical motion *skeleton*

(Ant model courtesy Hou Soon Ming)

---

---

---

---

---

---

---

---

## Grab a Motion.

- Off the web
- Freshly captured
- From company moCap archives
- Must be hierarchical and humanoid in nature

---

---

---

---

---

---

---

## Size up the Situation.

- Our chosen character size and motion size are clearly different

---

---

---

---

---

---

---

## Resize the Mesh?

- Simple to do
- If limb proportions differ, this leads to distortion

---

---

---

---

---

---

---

## Resize the Motion.

- Simple measurements lead to bone-length changes
- Leads to a few problems

---

---

---

---

---

---

---

---

## Wow! Done Already?

- The resized motion looks good, right?
- But wait, no poses in the motion match the character's pose...

---

---

---

---

---

---

---

---

## Assigning Motion to the Model.

- Could take arbitrary motion pose and rotate it into model's pose
- Could build a skeleton for the model from scratch with matching bone lengths

---

---

---

---

---

---

---

---

## Rotating Skeleton Into Place?

- Tedious process
- Difficult to get certain rotations correct (wrist, shoulders, etc)

---

---

---

---

---

---

---

## Building Skeleton From Scratch?

- Appears to be very easy
- The joint coordinate systems may not match

---

---

---

---

---

---

---

## Coordinate System Overview.

- Due to capture process and/or file format specifications, motions may have joint coordinate systems oriented in different directions
- This is best shown with examples

---

---

---

---

---

---

---

## Shoulder Example 1.

- A -90 degree rotation around the Z axis in this case yields the following:

---

---

---

---

---

---

---

## Shoulder Example 2.

- In this case, a 90 degree rotation around the X axis yields the same result as before:

---

---

---

---

---

---

---

## So...

- Though the previous skeletons looked identical, their rotation data was very different
- When building a skeleton from scratch, coordinate systems of the new skeleton must match the motion's
- **Very** difficult to accomplish

---

---

---

---

---

---

---

## Our Approach.

- Instead of a skeleton, create a point cloud of joints in the mesh
- Trivial for the user
- Works with nearly any 3d modeling package out there

---

---

---

---

---

---

---

---

## Our Approach - Prepare Motion.

- Need to pose the motion in a way which allows intuitive adjustments to match model's bind pose
- Zombie (or Frankenstein) pose

---

---

---

---

---

---

---

---

## Rotate the Motion's Skeleton.

- Rotate each bone in the motion to match model point cloud information
- Relies heavily on knowledge of humanoid kinematics
- Maintains coordinate systems

---

---

---

---

---

---

---

---

## Gotcha's With Our Approach.

- Heuristic relies on humanoid motion simplification
- Point cloud insufficient to convey all joint orientations
- If motion is not humanoid, humanoid kinematics do not apply

---

---

---

---

---

---

---

## Humanoid Motion Simplification.

- People's joints move in very complex ways
- Example: shoulder/elbow rotation

---

---

---

---

---

---

---

## Motion Simplification Contd.

- When rotating shoulder into position, it is very difficult to take all rotational degrees of freedom into account
- We only allow for rotation around two axes

---

---

---

---

---

---

---

## Motion Simplification Contd.

- Simplification problems manifest themselves in subtle ways

---

---

---

---

---

---

---

---

## Limb Forward Direction

- Hands, elbows, feet, and knees especially problematic
- Feet have a free guide – the toes point forward

---

---

---

---

---

---

---

---

## Limb Forward Direction Contd.

- Hands have no forward vector
- Easy to add forward point in cloud, but somewhat unintuitive

---

---

---

---

---

---

---

---

## Non-Humanoid Motion.

- Unless you know at least some of the complexities behind the creature's degrees of freedom, all bets are off

---

---

---

---

---

---

---

---

## Finally We Can Bind!

- Despite all the gotcha's, our technique still works quite well
- With our matching skeletons, any bone-based hierarchical skinning technique can be applied

---

---

---

---

---

---

---

---

## Now Are We Done?

- Most certainly not!
- The model is not interacting with its environment as it should
- Its feet are nowhere near the ground

---

---

---

---

---

---

---

---

## A Simple Transformation Fix?

- Model's root is still following old root translations
- A simple translation to the floor will yield sliding feet and too much bounce

---

---

---

---

---

---

---

## How Do We Fix This Mess?

- Constraint-based motion editing to the rescue!

---

---

---

---

---

---

---

## Constraints – What Are They?

- A place in the motion where some relation must be true
- Please Refer to Dr. Michael Gleicher's SIGGRAPH 1998 entitled *Retargeting Motion to New Characters* as well as the numerous others located in our bibliography

---

---

---

---

---

---

---

## Example...

- Grabbing an apple on a table
- We place a constraint between the hand of the character and the apple

---

---

---

---

---

---

---

## Example Contd.

- Shrinking the character, reveals that it cannot grab the apple with the same joint rotations

---

---

---

---

---

---

---

## Example Contd.

- With constraints satisfied (solved for), shorter character adaptively leans and stretches to grab apple

---

---

---

---

---

---

---

## Constraints and Our Example.

- In our case, adding constraints where the motion's feet hit the floor would probably be sufficient
- As seen before, our new mesh is clearly not satisfying its foot-hits-floor constraints

---

---

---

---

---

---

---

## Solving for the Constraints.

- A quick solve for the constraints yields our model walking nicely along the floor

---

---

---

---

---

---

---

## Tweaking Our Solution.

- Constraint-based motion editing is an interactive and iterative process
- Though constraints are met, motion may not be as we would like
- Further tweaking can be done

---

---

---

---

---

---

---

## Moving Constraints.

- Moving/scaling constraints to different positions may be more desirable

---

---

---

---

---

---

---

## Summary.

- Our approach from an artist's view :
  - Find **any** model and motion
  - Create a point cloud for the model (adding an extra point for the hands)
  - Run our pose-equating process
  - Create reasonable constraints
  - Run our constraint-solver
  - Tweak constraints until satisfied

---

---

---

---

---

---

---

## Advantages of Our Approach.

- Coding the pose-matching portion is straightforward
- Robustness – it works with nearly every humanoid motion
- Reuse – it can breathe new life into old motions
- Speed – once system is in place, many motions can be retargeted quickly

---

---

---

---

---

---

---

## Disadvantages of Our Approach.

- Coding an effective constraint-solver is very difficult
- Knowledge of motion's kinematics must be mastered before pose-matching can be universally effective

---

---

---

---

---

---

---
